

Layered Components Report

Boston Wyatt

3 October 2026

Site Details

My live layered components page is at <https://buttermylloaf23.github.io/advancedcss-portfolio/unit2/layered-components/index.html> and the source code is at <https://github.com/ButterMyLoaf23/advancedcss-portfolio/tree/main/unit2/layered-components>.

Reflections

Layer Declaration with Vendor CSS

The vendor layer contains CSS from a library. I would put it first so that my CSS can override the library if it needs to. The base layer contains the body, headings, and links. The components layer contains all of my styles for cards, buttons, forms, and navigation. Lastly, the utilities layer would just contain my smaller classes that override the component styles when needed. This makes sense to me because it changes it from general styling to a more specific styling on this page.

:is() vs :where()

Both :is() and :where() can be used to be group selectors and can avoid repeating the same CSS. The difference is that :is() is more specific and :where() is not specific. In my assignment, I just used :is() to style my page text input area with the same style. If I was writing this for other developers, I would use :where() because since it is less specific, it would make it more easy to override some base styles.

Rethinking Unit 1

One thing I would change from Unit 1 is that I would separate my custom properties into different files to keep it more organized and easier to find different CSS files and styles. I would definitely make a colors.css file and variable.css file to be more organized with those and have a distinguished way of finding those styles.
